Abstract

A simple and commonly used method to approximate the total claim distribution of a (possible weakly dependent) insurance collective is the normal approximation. In this article, we investigate the error made when the normal approximation is plugged in a fairly general distribution-invariant risk measure. We focus on the rate of the convergence of the error relative to the number of clients, we specify the relative error's asymptotic distribution, and we illustrate our results by means of a numerical example. Regarding the risk measure, we take into account distortion risk measures as well as distribution-invariant coherent risk measures.

Keywords: Total claim distribution, ϕ- and α-mixing sequences of random variables, normal approximation, nonuniform Berry-Esseen inequality, distortion risk measure, coherent risk measure, robust representation.

1 Introduction

In insurance practice, a simple and fast way to approximate the distribution of the total claim amount $S_n := \sum_{i=1}^{n} X_i$ of a homogeneous (possibly weakly dependent) insurance collective $\{X_1, \ldots, X_n\}$ is the normal approximation. According to the CLT we have that the distribution of S_n is "close" (relatively to n) to the normal distribution with mean $\mu_n := \mathbb{E}[S_n] = n\mathbb{E}[X_1]$ and variance $\sigma_n^2 := \mathbb{V}\text{ar}[S_n]$, provided the latter is finite. Practitioners then often plug this normal distribution $\mathcal{N}_{\mu_n, \sigma_n^2}$ in some distribution-invariant risk measure ρ to approximate the collective's premium $\rho(F_n)$ by $\rho(\Phi_n)$, where F_n and $\Phi_n := \Phi_{\mu_n, \sigma_n^2}$ refer to the distribution functions (df) of S_n and $\mathcal{N}_{\mu_n, \sigma_n^2}$, respectively. Actually, the values of μ_n and σ_n have to be estimated by some suitable estimators $\hat{\mu}_n = \hat{\mu}_{n,m_n}$ and $\hat{\sigma}_n = \hat{\sigma}_{n,m_n}$ (based on a sample of size m_n) and the resulting (random) df $\hat{\Phi}_n := \Phi_{\hat{\mu}_n, \hat{\sigma}_n^2}$ is plugged in the risk measure to approximate the collective's premium. Notice that for positively homogeneous and cash-invariant risk measures, the approximation $\rho(\hat{\Phi}_n)$ can be expressed as

$$\rho(\hat{\Phi}_n) = \hat{\sigma}_n \, \rho(\Phi) - \hat{\mu}_n \tag{1}$$

where Φ refers to the standard normal df. The representation (1) provides an extremely simple tool for the approximation of the collective's premium $\rho(F_n)$, so that this (normal) approximation is quite popular in practice.

In this article we focus on how the error distance between $\rho(\hat{\Phi}_n)$ and $\rho(F_n)$ behaves asymptotically, relatively to n, as the number n of clients increases. For a large class of distribution-invariant positively homogeneous and cash-invariant risk measures ρ (in the sense of [1, 2, 8, 13]) we will show that under fairly mild assumptions

$$n^{1/2-\varepsilon} \, \frac{\rho(\hat{\Phi}_n) - \rho(F_n)}{n} \xrightarrow{a.s.} 0, \qquad n \to \infty \tag{2}$$

for each $\varepsilon \in (0, 1/2)$, and

$$\text{law}\Big(n^{1/2} \, \frac{\rho(\hat{\Phi}_n) - \rho(F_n)}{n} \Big) \xrightarrow{w} \mathcal{N}, \qquad n \to \infty \tag{3}$$

for a certain normal distribution $\mathcal{N}$. Notice that $\rho_g(\hat{\Phi}_n)/n$ can be seen as an approximation of the individual premium $\rho_g(F_n)/n$.

Regarding ρ we will at first focus on so called distortion risk measures introduced by Wang [36]. Given a distortion function g, i.e. a nondecreasing function g on $[0, 1]$ satisfying $g(0) = 0$ and $g(1) = 1$,

$$\rho_g(F) := \int_{-\infty}^{0} g(F(t)) \, dt - \int_{0}^{\infty} [1 - g(F(t))] \, dt \tag{4}$$

provides a positively homogeneous distribution-invariant monetary risk measure on the class $\mathbb{F}_g$ of all df F for which the integrals in (4) exists. It is subadditive (hence coherent) if and only if g is concave (cf. [37]). As usual we refer to ρ_g as distortion risk measure with distortion function g. If g is a càdlàg function then we have the alternative representation $\rho_g(F) = -\int_{\mathbb{R}} x \, dg(F(x))$. Notice that most of the popular

risk measures in practice can be represented as in (4), so that this class of risk measures has been studied extensively in the last decade, see [16, 19, 20, 36, 37, 38] and references cited therein. For instance, the Value-at-Risk VaR_α at level $\alpha \in (0,1)$, the Average Value-at-Risk AVaR_α at level $\alpha \in (0,1)$, and the Wang transform WT_θ with parameter $\theta \in \mathbb{R}$, correspond to the distortion functions $g(x) = \mathbb{1}_{[\alpha,1]}(x)$, $g(x) = (x/\alpha) \wedge 1$, and $g(x) = \Phi(\Phi^{-1}(x) - \theta)$, respectively. For details and other examples see, e.g., [19, 38]. In Section 2.1, we will establish (2) and (3) for $\rho = \rho_g$. We will see in particular that the goodness of the approximation of $\rho(F_n)/n$ by $\rho(\hat{\Phi}_n)/n$ is typically ruled by the goodness of the estimate $\hat{\mu}_n/n$ of $\mathbb{E}[X_1]$ (cf. Corollary 2.9 and its proof). In Section 2.2 we will see that the results of Section 2.1 can easily be extended to partially more general distribution-invariant risk measures. The key will be a robust representation (similar to results in [13]) of distribution-invariant coherent risk measures by distortion risk measures. In Section 3, we will illustrate our analysis by means of a numerical example, and in Section 4 we will give the proofs of our main results. Finally, in the Appendix A we will present some examples for risk measures that match the setting of Section 2.2.

2 Results

Let $X_1, X_2, \ldots$ be identically distributed square-integrable random variables on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$. The random variable X_i can be regarded as the claim of the ith client, where a negative value corresponds to a payout to the client. We denote by F_n the df of the total claim amount $S_n := \sum_{i=1}^n X_i$, let $\hat{\mu}_n$ and $\hat{\sigma}_n$ be some estimates of $\mu_n := \mathbb{E}[S_n] = n\mathbb{E}[X_1]$ and $\sigma_n := \mathbb{V}\text{ar}[S_n]^{1/2}$ (based on a sample of size m_n), and let Φ, Φ_n and $\hat{\Phi}_n$ denote the standard normal df, the df of $\mathcal{N}_{\mu_n, \sigma_n^2}$ and the (random) df of $\mathcal{N}_{\hat{\mu}_n, \hat{\sigma}_n^2}$, respectively.

Throughout this article we will assume that the sequence (X_i) is "(λ, γ)-Berry-Esseen". We say that (X_i) is (λ, γ)-Berry-Esseen if there is some constant $c_{\lambda, \gamma} > 0$ such that $\|G_n - \Phi\|_\lambda \le c_{\lambda, \gamma} \, n^{-\gamma}$ for all $n \in \mathbb{N}$, where G_n denotes the df of the random variable $Z_n := (S_n - \mu_n)/\sigma_n$, and $\| \cdot \|_\lambda := \|(\cdot)\phi_\lambda\|_\infty$ refers to the nonuniform sup-norm based on the weight function $\phi_\lambda(x) := (1 + |x|)^\lambda$, $x \in \mathbb{R}$. In Example 2.1 we will give three examples for Berry-Esseen sequences. Two of them involve the notion of ϕ- and α-mixing introduced in [18] and [32], respectively. Recall that (X_i) is said to be ϕ- or α-mixing according to as $\phi(n) \to 0$ or $\alpha(n) \to 0$, respectively, where

$$
\begin{aligned}
\phi(n) &:= \sup_{k \ge 1} \sup_{A \in \mathcal{F}_1^k, \, B \in \mathcal{F}_{n+k}^\infty} |\mathbb{P}[B|A] - \mathbb{P}[B]| \\
\alpha(n) &:= \sup_{k \ge 1} \sup_{A \in \mathcal{F}_1^k, \, B \in \mathcal{F}_{n+k}^\infty} |\mathbb{P}[A \cap B] - \mathbb{P}[A]\mathbb{P}[B]|
\end{aligned}
$$

with $\mathcal{F}_n^m := \sigma(X_i : n \le i \le m) \subset \mathcal{F}$. For an overview on mixing conditions see, e.g., [4, 9]. In [5], one can find several examples for strictly stationary ϕ-mixing sequences (noting that ϕ-mixing sequences are also β-mixing, cf. [4, (1.11)]). For examples for strictly stationary α-mixing sequences see, e.g., [24].

Example 2.1 (i) If $X_1, X_2, \ldots$ are independent and $\mathbb{E}[|X_1|^{2+\delta}] < \infty$ for some $\delta > 0$, then Michel's nonuniform Berry-Esseen inequality [25, Theorem 3] shows that (X_i) is (λ, γ)-Berry-Esseen with $\lambda = 2 + \delta$ and $\gamma = \min\{\delta; 1\}/2$.

(ii) If (X_i) is strictly stationary and ϕ-mixing with mixing coefficients $\phi(n)$ satisfying $\phi(n) \leq c\, e^{-\kappa n}$ for all $n \in \mathbb{N}$ and some $c, \kappa > 0$, $\mathbb{E}[|X_1|^{2+\delta}] < \infty$ for some $\delta \geq 1$, and $\lim_{n \to \infty} \sigma_n / \sqrt{n} = \sigma$ for some $\sigma > 0$, then Schneider's nonuniform Berry-Esseen inequality [34, Theorem 4] shows that (X_i) is (λ, γ)-Berry-Esseen for $\lambda = 2 + \delta$ and $\gamma \in (0, 1/2)$. Notice that under the assumptions imposed on $\phi(n)$ we have that $\sigma_n / \sqrt{n}$ converges to $\sigma := (\mathbb{V}\mathrm{ar}[X_1] + 2 \sum_{j=2}^{\infty} \mathbb{C}\mathrm{ov}(X_1, X_j))^{1/2}$, cf. Example 2.5(ii) below.

(iii) If (X_i) is strictly stationary and α-mixing with mixing coefficients $\alpha(n)$ satisfying $\sum_{n=1}^{\infty} \alpha(n)^{\varepsilon} < \infty$ for all $\varepsilon > 0$, $\mathbb{E}[|X_1|^q] < \infty$ for all $q > 0$, and $\lim_{n \to \infty} \sigma_n / \sqrt{n} = \sigma$ for some $\sigma > 0$, then Hipp's nonuniform Berry-Esseen inequality [17, Theorem 2.5] shows that (X_i) is (λ, γ)-Berry-Esseen for every $\lambda > 0$ and $\gamma \in (0, 1/2)$. Notice that under the assumptions imposed on $\alpha(n)$ we have that $\sigma_n / \sqrt{n}$ converges to $\sigma := (\mathbb{V}\mathrm{ar}[X_1] + 2 \sum_{j=2}^{\infty} \mathbb{C}\mathrm{ov}(X_1, X_j))^{1/2}$, cf. Example 2.5(iii) below. $\diamond$

2.1 Distortion risk measures

In this subsection we focus on distortion risk measures ρ_g as introduced in (4). We first investigate the distance between $\rho_g(\Phi_n)$ and $\rho_g(F_n)$. As usual, $a \wedge b$ and $a \vee b$ denote the minimum and the maximum of $a, b \in \mathbb{R}$, respectively. Moreover we set $a^+ := a \vee 0$ and $a^- := (-a) \vee 0$ for $a \in \mathbb{R}$.

Theorem 2.2 *Let g be a distortion function, and suppose that*

(a) *there are $L, \beta > 0$, $k \in \mathbb{N}_0$, and $0 = d_0 < d_1 < \ldots < d_{k+1} = 1$, such that g is Hölder-β-continuous with Hölder constant L on each of the intervals (d_i, d_{i+1}), $i = 0, \ldots, k$,*

(b) *(X_i) is (λ, γ)-Berry-Esseen for some $\gamma > 0$ and $\lambda \geq 1$ satisfying $\lambda\beta > 1$,*

(c) *$\lim_{n \to \infty} \sigma_n / \sqrt{n} = \sigma$ for some $\sigma > 0$,*

(d) *$F_n \in \mathbb{F}_g$ and $\Phi_n \in \mathbb{F}_g$ for all $n \in \mathbb{N}$.*

Then there is some finite constant $C = C_{k, L, \lambda, \gamma, \beta, \sigma} > 0$, and some $n_0 \in \mathbb{N}$ (depending only on the distribution of X_1), such that

$$|\rho_g(F_n) - \rho_g(\Phi_n)| \leq C\, n^{1/2 - (\beta \wedge 1)\gamma} \qquad \forall n \geq n_0. \tag{5}$$

If g is Hölder-β-continuous on all of $[0, 1]$, i.e. if $k = 0$, then in (b) the assumption $\lambda \geq 1$ can be replaced by $\lambda > 0$, in the exponent on the right-hand side of (5) the expression $\beta \wedge 1$ can be replaced by β, and inequality (5) holds for all $n \in \mathbb{N}$.

The proof of Theorem 2.2 is relegated to Section 4.1. Assumption (d) in Theorem 2.2 is imposed to guarantee that the left-hand side of (5) is well-defined. In the following Examples 2.3–2.6 we illustrate conditions (a)–(d), respectively.

Example 2.3 Condition (a) on g in Theorem 2.2 is fulfilled for, e.g., $g_1(x) = \mathbb{1}_{[\alpha,1]}(x)$ (Value-at-Risk), $g_2(x) = (x/\alpha) \wedge 1$ (Average Value-at-Risk) and $g_3(x) = \Phi(\Phi^{-1}(x) - \theta)$ (Wang transform) with any $\beta > 0$, $\beta = 1$ and $\beta \in (0,1)$, respectively. $\diamond$

Example 2.4 (i) If $X_1, X_2, \dots$ are independent and $\mathbb{E}[|X_1|^{(2+\delta) \vee (1/\beta)}] < \infty$ for some $\delta > 0 \vee (1/\beta - 2)$, then according to Example 2.1(i) the sequence (X_i) satisfies condition (b) in Theorem 2.2 with $\lambda = 2 + \delta$ and $\gamma = (\delta \wedge 1)/2$.

(ii) If (X_i) is strictly stationary and ϕ-mixing with mixing coefficients $\phi(n)$ satisfying $\sum_{n=1}^{\infty} \phi(n)^{1/2} < \infty$, and $\mathbb{E}[|X_1|^{2+\delta}] < \infty$ for some $\delta > 1 \vee (1/\beta - 2)$, then according to Example 2.1(ii) the sequence (X_i) subject to condition (c) in Theorem 2.2 satisfies condition (b) in Theorem 2.2 with $\lambda = 2 + \delta$ and $\gamma \in (0, 1/2)$.

(iii) If (X_i) is strictly stationary and α-mixing with mixing coefficients $\alpha(n)$ satisfying $\sum_{n=1}^{\infty} \alpha(n)^{\varepsilon} < \infty$ for every $\varepsilon > 0$, and $\mathbb{E}[|X_1|^q] < \infty$ for every $q > 0$, then according to Example 2.1(iii) the sequence (X_i) subject to condition (c) in Theorem 2.2 satisfies condition (b) in Theorem 2.2 with $\lambda > 1/\beta$ and $\gamma \in (0, 1/2)$. $\diamond$

Example 2.5 (i) If $X_1, X_2, \dots$ are independent then the sequence (X_i) clearly satisfies condition (c) in Theorem 2.2 for $\sigma := \mathbb{V}\mathrm{ar}[X_1]^{1/2}$.

(ii) If (X_i) is strictly stationary and ϕ-mixing with mixing coefficients $\phi(n)$ satisfying $\sum_{n=1}^{\infty} \phi(n)^{1/2} < \infty$, and $\mathbb{E}[|X_1|^{2+\delta}] < \infty$ for some $\delta > 0$, then the sequence (X_i) satisfies condition (c) in Theorem 2.2 for $\sigma := (\mathbb{V}\mathrm{ar}[X_1] + 2 \sum_{j=2}^{\infty} \mathbb{C}\mathrm{ov}(X_1, X_j))^{1/2}$, see the proof of Lemma 4.2.2 in [29].

(iii) If (X_i) is strictly stationary and α-mixing with mixing coefficients $\alpha(n)$ satisfying $\sum_{n=1}^{\infty} \alpha(n)^{\delta/(2+\delta)} < \infty$ for some $\delta > 0$, and $\mathbb{E}[|X_1|^{2+\delta}] < \infty$, then the sequence (X_i) satisfies condition (c) in Theorem 2.2 for $\sigma := (\mathbb{V}\mathrm{ar}[X_1] + 2 \sum_{j=2}^{\infty} \mathbb{C}\mathrm{ov}(X_1, X_j))^{1/2}$, see [27, Corollary 1.1]. $\diamond$

Example 2.6 If there are $0 < x_0 \leq x_1 < 1$ so that $g(x) = 0$ for $x \in [0, x_0)$ and $g(x) = 1$ for $x \in (x_1, 1]$ (which is the case, e.g., for g_1 in Example 2.3), then condition (d) in Theorem 2.2 is always fulfilled. Moreover, if $F_1 \in \mathbb{F}_g$ and $\Phi \in \mathbb{F}_g$ then condition (d) is also fulfilled whenever g is concave (which is the case, e.g., for g_2 and g_3 in Example 2.3). Indeed in this case ρ_g may be viewed as a Choquet integral w.r.t. the set function $g(\mathbb{P}[\cdot])$ (cf. [13]), and the space of random variables on $(\Omega, \mathcal{F}, \mathbb{P})$ with df in $\mathbb{F}_g$ is a vector subspace of the space of all random variables on $(\Omega, \mathcal{F}, \mathbb{P})$ (cf. [7]). $\diamond$

We emphasize that in the setting of Example 2.4(i), for each of the risk measures ρ_{g_i} in Example 2.3 the right-hand side of (5) is strictly positive and bounded below. This is also true for every coherent distortion risk measures since the concavity of g implies $\beta \leq 1$. For g_1 and g_2 in Example 2.3, and for all other distortion functions g for which we can choose $\beta = 1$, the right-hand side of (5) can even be chosen to be constant (provided $\gamma \geq 1/2$, e.g., if $\delta \geq 1$ in the setting of Example 2.4). So in this case the

relative error $|\rho_g(F_n) - \rho_g(\Phi_n)|/n$ converges at least at rate 1. On the other hand, in general, no matter how small $\beta, \gamma > 0$ are, the relative error converges always faster than at rate $1/2$.

As indicated in the introduction, in practice one is actually interested in statements as (2) where μ_n and σ_n are estimated by some suitable estimators $\hat{\mu}_n$ and $\hat{\sigma}_n$ based on random variables $Y_1, \ldots, Y_{m_n}$ having the same distribution as X_1. We will assume throughout the rest of this section that

$$n^{-(1/2+\varepsilon)}(\hat{\mu}_n - \mu_n) \xrightarrow{a.s.} 0 \tag{6}$$

for some $\varepsilon \in (0, 1/2)$, and that

$$n^{-1/2}(\hat{\sigma}_n - \sigma_n) \xrightarrow{a.s.} 0. \tag{7}$$

The following two examples show that the conditions (6)–(7) are not too restrictive. Throughout theses examples we shall assume $m_n \sim n$, i.e. that there is some constant $c > 0$ such that $m_n/n \to c$ as $n \to \infty$.

Example 2.7 (i) If $Y_1, Y_2, \ldots$ are independent, then (6) holds for $\hat{\mu}_n := \frac{n}{m_n} \sum_{i=1}^{m_n} Y_i$ and every $\varepsilon \in (0, 1/2)$ by the Marcinkiewicz-Zygmund SLLN (cf. [11, 35]) and Slutzky's lemma.

(ii) If (Y_i) is strictly stationary and ϕ-mixing with mixing coefficients $\phi(n)$ satisfying $\sum_{n=1}^{\infty} \phi(2^n)^{1/2} < \infty$, then (6) holds for $\hat{\mu}_n := \frac{n}{m_n} \sum_{i=1}^{m_n} Y_i$ and every $\varepsilon \in (0, 1/2)$ by Peligrad's Marcinkiewicz-Zygmund type SLLN for strictly stationary ϕ-mixing sequences [26, Theorem 2] and Slutzky's lemma.

(iii) If (Y_i) is strictly stationary and α-mixing with mixing coefficients $\alpha(n)$ satisfying $\sum_{n=1}^{\infty} n^{(1-4\varepsilon)/(2\varepsilon)}\alpha(n) < \infty$ for some $\varepsilon \in (0, 1/2)$, then (6) holds for $\hat{\mu}_n := \frac{n}{m_n} \sum_{i=1}^{m_n} Y_i$ (with the same ε) by Rio's Marcinkiewicz-Zygmund type SLLN for strictly stationary α-mixing sequences (cf. [31, Theorem 1 along with (1.10) with $r = 2$]) and Slutzky's lemma. $\diamond$

Example 2.8 (i) If $X_1, X_2, \ldots$ are independent and $Y_1, Y_2, \ldots$ are independent, then (7) holds for $\hat{\sigma}_n := (\frac{n}{m_n} \sum_{i=1}^{m_n} (Y_i - \frac{1}{m_n} \sum_{i=1}^{m_n} Y_i)^2)^{1/2}$ by the classical Kolmogorov SLLN and Slutzky's lemma.

(ii) If the sequences (X_i) and (Y_i) coincide in law, (X_i) is strictly stationary and α-mixing with mixing coefficients $\alpha(n)$ satisfying $\sum_{n=1}^{\infty} \alpha(n)^{\delta/(2+\delta)} < \infty$ for some $\delta > 0$, and $\mathbb{E}[|X_1|^{2+\delta}] < \infty$, then (7) holds for $\hat{\sigma}_n := \sqrt{\frac{\pi}{2}} \frac{\sqrt{n}}{\log m_n} \sum_{i=1}^{m_n} \frac{1}{\sqrt{i}}|\frac{1}{i} \sum_{j=1}^{i} Y_j - \frac{1}{m_n} \sum_{i=1}^{m_n} Y_i|$ by Corollary 1.1 in [27] and Slutzky's lemma. $\diamond$

Corollary 2.9 (Rate of convergence) *Suppose that the assumptions of Theorem 2.2 and the conditions (6) and (7) hold. Then we have (2) with $\rho = \rho_g$ (and ε as in (6)), i.e.*

$$n^{1/2-\varepsilon} \frac{\rho_g(\hat{\Phi}_n) - \rho_g(F_n)}{n} \xrightarrow{a.s.} 0, \qquad n \to \infty.$$

Proof By the triangle inequality, the representation (1) for $\rho_g(\Phi_n)$ (recall that ρ_g is the positively homogeneous and cash-invariant), the analogous representation for $\rho_g(\Phi_n)$, and (5), we have

$$\frac{|\rho_g(\hat{\Phi}_n) - \rho_g(F_n)|}{n} \quad \leq \quad \frac{|\rho_g(\hat{\Phi}_n) - \rho_g(\Phi_n)|}{n} + \frac{|\rho_g(\Phi_n) - \rho_g(F_n)|}{n}$$

$$\leq \quad \frac{|\hat{\sigma}_n - \sigma_n|\,|\rho_g(\Phi)| + |\mu_n - \hat{\mu}_n|}{n} + C\,n^{-1/2 - (\beta \wedge 1)\gamma} \quad (8)$$

with Φ the standard normal df. By (6) we have that $|\mu_n - \hat{\mu}_n|/n$ converges to 0 at least at rate $1/2 - \varepsilon$. By (7) we have that $|\hat{\sigma}_n - \sigma_n|/n$ converges to 0 at least at rate $1/2$. Moreover we obviously have that the latter summand on the right-hand side of (8) converges to 0 at rate $1/2 + (\beta \wedge 1)\gamma$. The statement of Corollary 2.9 then follows from (8). $\qquad \square$

Corollary 2.9 and its proof show that the rate of the convergence of $(\rho_g(\Phi_n) - \rho_g(F_n))/n$ to 0 is not smaller than the rate of the convergence of the estimator $\hat{\mu}_n/n$ to $\mathbb{E}[X_1]$. We realize that in this case the relative approximation of $\rho_g(F_n)$ by $\rho_g(\Phi_n)$ is asymptotically not worse than the estimation of the mean $\mathbb{E}[X_1]$. We can also deduce that if

$$\mathrm{law}\Big(\sqrt{n}\,\frac{\hat{\mu}_n - \mu_n}{n}\Big) \xrightarrow{w} \mathcal{N}, \qquad n \to \infty \quad (9)$$

for some distribution $\mathcal{N}$ on $(\mathbb{R}, \mathcal{B}(\mathbb{R}))$, then the asymptotic error distribution $\mathcal{N}$ in (3) is given by the same $\mathcal{N}$, cf. Corollary 2.10. Notice that assumption (9) is not too restrictive. Indeed: For $\hat{\mu}_n := \frac{n}{m_n}\sum_{i=1}^{m_n} Y_i$ the Examples 2.1 and 2.5 provide standard settings where (9) holds for $\mathcal{N} = \mathcal{N}_{0,\sigma^2}$ (just replace (X_i) by (Y_i)), and Example 2.8 shows that in some situations it is even possible to estimate the asymptotic standard deviation σ consistently.

Corollary 2.10 (Asymptotic error distribution) *Suppose the assumptions of Theorem 2.2 and the conditions (7) and (9) hold. Then we have (3) with $\rho = \rho_g$, i.e.*

$$\mathrm{law}\Big(\sqrt{n}\,\frac{\rho_g(\hat{\Phi}_n) - \rho_g(F_n)}{n}\Big) \xrightarrow{w} \mathcal{N}, \qquad n \to \infty.$$

Proof The statement of Corollary 2.10 follows immediately from (8) (without absolute values and with "$\leq$" replaced by "$=$"), condition (9) and Slutzky's lemma. $\qquad \square$

Remark 2.11 It is worth mentioning that the normal approximation makes sense also for parametric models for the distribution of X_1 since the convolution is typically non-determinable. For parametric models the estimators $\hat{\mu}_n$ and $\hat{\sigma}_n$ might be chosen according to the particular model (and might possess partially better statistical properties compared to the nonparametric estimators considered in Examples 2.7 and 2.8), but the asymptotic behavior of the estimators exploited in the corollaries is typically the same. $\qquad \diamond$

2.2 Extension to partially more general distribution-invariant risk measures

In this section, we focus on distribution-invariant coherent risk measures ρ that are not necessarily distortion risk measures but that can be robustly represented by distortion risk measures (more precisely by concave distortion functions). That is, we suppose that there exists a set $\mathcal{G}_\rho$ of concave distortion functions such that

$$\rho(F) = \sup_{g \in \mathcal{G}_\rho} \rho_g(F) \tag{10}$$

for every admissible df F, where ρ_g denotes the distortion risk measure with distortion function g (cf. (4)). So we have in particular

$$|\rho(F_n) - \rho(\Phi_n)| = |\sup_{g \in \mathcal{G}_\rho} \rho_g(F_n) - \sup_{g \in \mathcal{G}_\rho} \rho_g(\Phi_n)| \leq \sup_{g \in \mathcal{G}_\rho} |\rho_g(F_n) - \rho_g(\Phi_n)|.$$

Now, observe that the constant C in the basic Theorem 2.2 depends only on β and L (other properties of g do not play any role). Therefore the result of Theorem 2.2 carries over to ρ in (10) if, for some $\beta > 0$ fixed, all distortion functions $g \in \mathcal{G}_\rho$ are Hölder-β-continuous with a common Hölder constant L. Of course, in this case the Corollaries 2.9 and 2.10 carry over to ρ in (10) as well. In Theorem 2.12 we will see that under some assumptions on ρ the robust representation (10) holds. In Lemma 2.14 we will obtain a criterion to check whether the distortion functions in $\mathcal{G}_\rho$ are all Hölder-β-continuous with a common Hölder constant L.

We first discuss the existence of the representation (10). Such a representation result is already known from [13] but we will give a generalized version; notice that (10) differs from the celebrated Kusuoka representation (see [23], and [28] for an extension). The basic setting is the following. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space that is rich enough to support a random variable with continuous distribution (which is equivalent to $(\Omega, \mathcal{F}, \mathbb{P})$ being atomless in the sense of [13, Definition A.26]). Let $\mathfrak{X}$ be a subspace of $\mathcal{L}^1(\Omega, \mathcal{F}, \mathbb{P})$ such that $\mathcal{L}^\infty(\Omega, \mathcal{F}, \mathbb{P}) \subset \mathfrak{X}$ and $X \wedge Y, X \vee Y \in \mathfrak{X}$ for all $X, Y \in \mathfrak{X}$, and let $\mathfrak{X}_+$ be the class of all nonnegative random variables of $\mathfrak{X}$. We denote by $\mathbb{F}$ the set of all df F_X of random variables $X \in \mathfrak{X}$, and we consider a distribution-invariant coherent risk measure $\rho : \mathbb{F} \to \mathbb{R}$. Finally we denote by B_x any random variable distributed according to the Bernoulli distribution with parameter x. Recall that every nondecreasing concave function on $[0, 1]$ is continuous on $(0, 1)$.

Theorem 2.12 (Robust representation) *If the cutting condition*

$$\lim_{n \to \infty} \rho(F_{-\lambda(X-n)^+}) = 0 \qquad \forall X \in \mathfrak{X}_+, \lambda > 0 \tag{11}$$

holds then there is some set $\mathcal{G}_\rho$ of concave distortion functions satisfying (10) for all $F \in \mathbb{F}$. If in addition

$$\lim_{x \to 0+} \rho(F_{-B_x}) = 0, \tag{12}$$

then all functions $g \in \mathcal{G}_\rho$ are continuous at 0 (and therefore continuous on $[0, 1]$).

The proof of Theorem 2.12 is relegated to Section 4.2. In Lemma A.1 in the Appendix A we will see that if $\mathfrak{X}$ is chosen to be an Orlicz space with continuous Young function, then every coherent risk measure ρ satisfies the conditions (11)–(12). In the Appendix A we will also give examples of particular coherent risk measures on Orlicz spaces satisfying (11)–(12). Further, we note that it is an easy consequence of (14) below that condition (12) ensures that the functions $g \in \mathcal{G}_\rho$ are continuous at 0 (i.e. that the second part of Theorem 2.12 holds true), where

$$\widetilde{g}_\rho(x) := \sup_{g \in \mathcal{G}_\rho} g(x), \qquad x \in [0,1]. \tag{13}$$

Notice that the function $\widetilde{g}_\rho$ is again a distortion function which we refer to as distortion function associated with ρ. We reasonably denote the corresponding distortion risk measure by $\rho_{\widetilde{g}_\rho}$.

Remark 2.13 (i) If ρ is known to be a distortion risk measure (as defined in (4)) then its distortion function g_ρ can clearly be recovered from ρ by $g_\rho(x) = \rho(F_{-B_x})$, $x \in [0,1]$, where as above B_x refers to any random variable distributed according to the Bernoulli distribution with parameter x.
(ii) If the risk measure ρ satisfies (10) for all $F \in \mathbb{F}$, then ρ will degenerate to a distortion risk measure if and only if $\rho = \rho_{\widetilde{g}_\rho}$ with $\widetilde{g}_\rho$ as in (13). The necessity is obvious, and the sufficiency can be seen as follows. If ρ is a distortion risk measure then according to (i) its distortion function g_ρ is given by $g_\rho(x) = \rho(F_{-B_x})$, $x \in [0,1]$. The identity (14) in Lemma 2.14 below then shows that g_ρ must coincide with the distortion function $\widetilde{g}_\rho$ associated with ρ. $\qquad \diamond$

The following lemma gives a criterion for the distortion functions $g \in \mathcal{G}_\rho$ to be all Hölder-β-continuous with a common Hölder constant.

Lemma 2.14 *Suppose (10) holds for all $F \in \mathbb{F}$ for some set $\mathcal{G}_\rho$ of concave distortion functions, and let $\widetilde{g}_\rho$ denote the distortion function associated with ρ (cf. (13)). Then we have*

$$\widetilde{g}_\rho(x) = \rho(F_{-B_x}), \qquad x \in [0,1], \tag{14}$$

where as above B_x refers to any random variable distributed according to the Bernoulli distribution with parameter x. Moreover, if every $g \in \mathcal{G}_\rho$ is continuous at 0, and if for some $\beta > 0$ the condition

$$L := \sup_{x \in (0,1]} \frac{\widetilde{g}_\rho(x)}{x^\beta} < \infty \tag{15}$$

holds, then every $g \in \mathcal{G}_\rho$ is Hölder-β-continuous with Hölder constant L.

The proof of Lemma 2.14 is relegated to Section 4.3. Condition (15) provides a transparent condition in order to obtain a common Hölder constant. Equation (14) in turn provides a useful tool for the calculation of $\widetilde{g}_\rho(x)$; the values $\widetilde{g}_\rho(x)$, $x \in [0,1]$, are needed for checking condition (15). In the Appendix A, we will give examples for distribution-invariant coherent risk measures satisfying condition (15). Examples are Haezendonck risk measures and risk measures based on one-sided moments.

3 Numerical example

In this section, we are going to illustrate Theorem 2.2 as well as the Corollaries 2.9 and 2.10 by means of a numerical example. We consider an i.i.d. insurance collective of size n and assume that the individual claim df F_1 is given by the Gamma df on $\mathbb{R}_-$ (i.e., $-X_1 \sim \Gamma(a, b)$) with parameters $a = 4$ and $b = 0.004$. We note that the Gamma distribution is often used in insurance practice to model small to moderate individual claims (as for instance in third party car insurance or home contents insurance). The mean and the standard deviation of F_1 are given by $-a/b = -1'000$ and $\sqrt{a/b^2} = 500$. The n-fold convolution F_n of F_1 is known to be the Gamma df on $\mathbb{R}_-$ with parameters $na = 4n$ and $b = 0.004$, and the mean and the standard deviation of F_n are given by $-1'000 \, n$ and $\sqrt{na/b^2} = 500 \sqrt{n}$, respectively. As underlying "premium principle" we consider the Value-at-risk at level $\alpha = 0.05$ which is the distortion risk measure ρ_g with distortion function $g = \mathbb{1}_{[\alpha, 1]}$.

As already mentioned subsequent to Example 2.6, Theorem 2.2 indicates that under some assumptions (which are fulfilled in the present setting) the right-hand side of (5) can be chosen to be constant. The second row in Figure 1 shows that in our example the difference $\rho(\Phi_n) - \rho(F_n)$ is indeed nearly constant as n increases. That is, relative to the number of clients n, the approximation of $\rho(F_n)$ by $\rho(\Phi_n)$ is of order n^{-1}. Hence the approximation is pretty good, see also the first row in Figure 1.

However, in practice the exact mean and the exact standard deviations are unknown and have be to estimated. So, in fact, for practical purposes it is more interesting to study the asymptotic behavior of the difference $\rho(\hat{\Phi}_n) - \rho(F_n)$. The Corollaries 2.9 and 2.10 show that the approximation of $\rho(F_n)$ by $\rho(\hat{\Phi}_n)$ relative to the number of clients n is of order $n^{-1/2+\varepsilon}$ and that the relative difference $(\rho(\hat{\Phi}_n) - \rho(F_n))/n$ weighted by $n^{1/2}$ is asymptotically normal. Figure 2 shows that in our example the relative error $(\rho(\Phi_n) - \rho(F_n))/n$ indeed converges to 0, and that the relative error weighted by $n^{1/2}$ is indeed subject to a random fluctuation. Figure 2 also shows that the approximation of $\rho(F_n)$ by $\rho(\hat{\Phi}_n)$ is "aggressive", which might be due to the fact that the tail of the Gamma distribution is "heavier" than the tail of a normal distribution.

4 Proofs

4.1 Proof of Theorem 2.2

The proof of Theorem 2.2 relies on the following lemma which involves the left-continuous inverse $H^{\leftarrow}(x) := \inf\{t \in \mathbb{R} : H(t) \geq x\}$ of a df H.

Lemma 4.1 *([38, Theorem 2]) Let g be a distortion function, and suppose that*

  (i) *there are $\beta, L > 0$, $k \in \mathbb{N}_0$, and $0 = d_0 < d_1 < \ldots < d_{k+1} = 1$, such that g is Hölder-β-continuous with Hölder constant L on each of the intervals (d_i, d_{i+1}), $i = 0, \ldots, k$,*

  (ii) *$H, H_1, H_2, \ldots \in \mathbb{F}_g$,*

(iii) H is differentiable at $H^{\leftarrow}(d_i)$, and $H'(H^{\leftarrow}(d_i)) > 0$, for $i = 1, \ldots, k$,

(iv) $\|H_n - H\|_\infty \to 0$.

For every $\lambda \geq 1$ satisfying $\lambda\beta > 1$ there is a finite constant $c = c_{k,H,L,\lambda\beta} > 0$, and some $n_0 \in \mathbb{N}$ (for which $\|H_n - H\|_\infty$ is sufficiently small for all $n \geq n_0$), such that

$$|\rho_g(H_n) - \rho_g(H)| \leq c \, \|H_n - H\|_\lambda^{\beta\wedge 1} \qquad \forall n \geq n_0. \tag{16}$$

If g is Hölder-β-continuous on all of $[0,1]$, i.e. if $k = 0$, then condition (iv) can be skipped, the assumption $\lambda \geq 1$ can be replaced by $\lambda > 0$, in (16) the exponent $\beta \wedge 1$ can be replaced by β, and inequality (16) holds for all $n \in \mathbb{N}$.

Notice that under the assumptions of Lemma 4.1, the expression $\|H_n - H\|_\lambda$ might be infinite when $\lambda > 1$. Also, $\|H_n - H\|_\lambda \to 0$ implies condition (iv).

In order to prove Theorem 2.2 we set $Z_n := (S_n - \mu_n)/\sigma_n$ and write N_n for any random variable distributed according to the normal law $\mathcal{N}_{\mu_n,\sigma_n^2}$. We further define $Z := (N_n - \mu_n)/\sigma_n$ which is $\mathcal{N}_{0,1}$-distributed. As ρ_g is distribution-invariant, we may and do use without risk of ambiguity $\rho_g(Y)$ and $\rho_g(F_Y)$ as synonyms, where Y is any admissible random variable. By the positive homogeneity and the translation invariance of ρ_g we obtain

$$
\begin{aligned}
|\rho_g(F_n) - \rho_g(\Phi_n)| &= |\rho_g(S_n) - \rho_g(N_n)| \\
&= |\rho_g(\sigma_n Z_n + \mu_n) - \rho_g(\sigma_n Z + \mu_n)| \\
&= |\sigma_n \rho_g(Z_n) - \mu_n - (\sigma_n \rho_g(Z) - \mu_n)| \\
&= \sigma_n |\rho_g(Z_n) - \rho_g(Z)| \\
&= \sigma_n |\rho_g(G_n) - \rho_g(\Phi)|,
\end{aligned}
\tag{17}
$$

where G_n denotes the df of Z_n, and Φ is the standard normal df. Now, we intend to apply Lemma 4.1. We are going to show that the assumptions (i)–(iv) of Lemma 4.1 are fulfilled for $H := \Phi$ and $H_n := G_n$. Condition (i) is ensured by assumption (a) of Theorem 2.2, the validity of condition (ii) was already discussed subsequent to Theorem 2.2, and condition (iii) is obvious since Φ is strictly increasing and smooth. By assumption (b) of Theorem 2.2 we moreover have

$$\|G_n - \Phi\|_\lambda \leq c_{\lambda,\gamma} \, n^{-\gamma} \qquad \forall n \in \mathbb{N} \tag{18}$$

for some constant $c_{\lambda,\gamma} > 0$, so that condition (iv) of Lemma 4.1 holds too. Therefore the lemma implies

$$|\rho_g(G_n) - \rho_g(\Phi)| \leq c_{k,\Phi,L,\lambda\beta} \, \|G_n - \Phi\|_\lambda^{\beta\wedge 1} \qquad \forall n \geq n_0$$

for some constant $c_{k,\Phi,L,\lambda\beta} > 0$. Along with assumption (c) of Theorem 2.2 as well as (17) and (18), this implies (5).

4.2 Proof of Theorem 2.12

The verification of the second part of Theorem 2.12 was already given subsequent to Theorem 2.12. The proof of the first part relies on the following lemma.

Lemma 4.2 *Condition (11) implies*

$$\rho(F_X) = \sup_{m \in \mathbb{N}} \inf_{k \in \mathbb{N}} \rho(F_{[X^+ \wedge k] - [X^- \wedge m]}) \qquad \forall\, X \in \mathfrak{X}.$$

Proof In view of Proposition 6.6 in [22], condition (11) allows to apply Lemma 6.5 in [22]. Assertion .1 of this lemma gives $\sup_{m \in \mathbb{N}} \rho(F_{X^+ - [X^- \wedge m]}) = \rho(F_X)$, and assertion .2 of this lemma gives $\inf_{k \in \mathbb{N}} \rho(F_{[X^+ \wedge k] - [X^- \wedge m]}) = \rho(F_{X^+ - [X^- \wedge m]})$ for every $m \in \mathbb{N}$. The statement of Lemma 4.2 is obvious now. □

We will combine Lemma 4.2 with known representation results (mentioned above) for distribution-invariant coherent risk measures defined on the set $\mathbb{F}^\infty$ of all df F_X of random variables $X \in \mathcal{L}^\infty(\Omega, \mathcal{F}, \mathbb{P})$ in order to prove Theorem 2.12.

Proof (of Theorem 2.12) Possibly changing to a suitable probability space, we may assume that $L^2(\Omega, \mathcal{F}, \mathbb{P})$ is separable. Then in the specified setting, Corollary 4.72 in [13] along with Theorem 2.1 in [21] yields the existence of some set $\mathcal{G}$ of concave distortion functions such that (10) holds for all $F \in \mathbb{F}^\infty$. Now set

$$\widetilde{\rho}(F) := \sup_{g \in \mathcal{G}} \rho_g(F), \qquad F \in \mathbb{F}.$$

We are going to show that $\widetilde{\rho}$ provides a distribution-invariant coherent risk measure on $\mathbb{F}$ which coincides with ρ. We will proceed in two steps: First we will show that $\widetilde{\rho}$ is well-defined and defines a distribution-invariant coherent risk measure on $\mathbb{F}$ (which obviously satisfies $\widetilde{\rho} = \rho$ on $\mathbb{F}^\infty$). Second we will show that $\widetilde{\rho} = \rho$ on $\mathbb{F}$.

Step 1. If we can show that $\rho_g(F) \in \mathbb{R}$ (for all $g \in \mathcal{G}$) and $\sup_{g \in \mathcal{G}} \rho_g(F) < \infty$ for all $F \in \mathbb{F}$, then it follows easily that $\widetilde{\rho}$ defines a distribution-invariant coherent risk measure on $\mathbb{F}$, since every distortion risk measure ρ_g with concave distortion function g is coherent and distribution-invariant. Of course, in view of (4), the mentioned conditions hold if we can show

$$\sup_{g \in \mathcal{G}} \int_{-\infty}^{0} g(F(t))\, dt \le \rho(F_{-X^-}) \quad \text{and} \quad \forall\, g \in \mathcal{G}: \quad \int_{0}^{\infty} [1 - g(F(t))]\, dt < \infty \quad (19)$$

for all $F \in \mathbb{F}$. To verify the first statement in (19), we pick $X \in \mathfrak{X}$ (corresponding to $F_X \in \mathbb{F}$). For every $g \in \mathcal{G}$ we have

$$g(F_{-X^-}(t)) \le \liminf_{m \to \infty} g(F_{-[X^- \wedge m]}(t))$$

at every continuity point $t < 0$ of F_{-X^-}, since g as a concave function is lower semicontinuous. Using this and applying Fatou's lemma, we obtain

$$\sup_{g \in \mathcal{G}} \int_{-\infty}^{0} g(F_X(t))\, dt \quad \le \quad \sup_{g \in \mathcal{G}} \int_{-\infty}^{0} g(F_{-X^-}(t))\, dt$$

$$\leq \sup_{g \in \mathcal{G}} \int_{-\infty}^{0} \liminf_{m \to \infty} g\big(F_{-[X^- \wedge m]}(t)\big) \, dt$$

$$\leq \sup_{g \in \mathcal{G}} \liminf_{m \to \infty} \int_{-\infty}^{0} g\big(F_{-[X^- \wedge m]}(t)\big) \, dt$$

$$= \sup_{g \in \mathcal{G}} \liminf_{m \to \infty} \rho_g\big(F_{-[X^- \wedge m]}\big)$$

$$\leq \liminf_{m \to \infty} \rho\big(F_{-[X^- \wedge m]}\big)$$

$$\leq \rho(F_{-X^-}).$$

Hence the first statement in (19) holds indeed. To verify the second statement in (19), we pick $X \in \mathfrak{X}$ (corresponding to $F_X \in \mathbb{F}$) and we denote by g' the right-sided derivative of g. As g is a nondecreasing concave function, it is continuous on $(0, 1]$, so that

$$1 - g(F_X(t)) = g(1) - g(F_X(t)) \leq g'(F_X(t_0))[1 - F_X(t)] \qquad \forall t \geq t_0,$$

for any $t_0 > 0$ such that $F_X(t_0) > 0$. Moreover, the integral $\int_0^\infty [1 - F_X(t)]dt$ exists since $X \in \mathcal{L}^1(\Omega, \mathcal{F}, \mathbb{P})$. Hence,

$$\int_0^\infty [1 - g(F_X(t))] \, dt \leq \int_0^{t_0} [1 - g(F_X(t))] \, dt + g'(F_X(t_0)) \int_{t_0}^\infty [1 - F_X(t)] \, dt < \infty.$$

This shows that the second statement in (19) holds, too.

Step 2. Condition (11) on ρ ensures that the right-hand side of

$$0 \leq \widetilde{\rho}\big(F_{-\lambda(X-r)^+}\big) \leq \rho\big(F_{-\lambda(X-r)^+}\big)$$

converges to 0, as $r \to \infty$, for every $X \in \mathfrak{X}_+$ and $\lambda > 0$. Therefore condition (11) is also fulfilled by $\widetilde{\rho}$, and Lemma 4.2 applied to $\widetilde{\rho}$ implies $\rho = \widetilde{\rho}$ on $\mathbb{F}$. □

4.3 Proof of Lemma 2.14

Due to (10), Remark 2.13(i) and the definition of $\widetilde{g}_\rho$, we have

$$\rho(F_{-B_x}) = \sup_{g \in \mathcal{G}_\rho} \rho_g(F_{-B_x}) = \sup_{g \in \mathcal{G}_\rho} g(x) = \widetilde{g}_\rho(x), \qquad x \in [0, 1],$$

i.e. (14) holds.

In order to prove the second part of Lemma 2.14, we let $0 < x < x' \leq 1$. Since the underlying probability space $(\Omega, \mathcal{F}, \mathbb{P})$ was assumed to be rich enough to support a random variable with continuous distribution, we may pick a measurable decomposition $\Omega_1 \cup \Omega_2 \cup \Omega_3$ of Ω such that $\mathbb{P}[\Omega_1] = x$, $\mathbb{P}[\Omega_2] = x' - x$ and $\mathbb{P}[\Omega_3] = 1 - x'$. We now define random variables $B_x := \mathbb{1}_{\Omega_1}$, $B_{x'} := \mathbb{1}_{\Omega_1 \cup \Omega_2}$ and $B_{x'-x} := \mathbb{1}_{\Omega_2}$, and note that they are distributed according to the Bernoulli distribution with parameters x, x' and $x' - x$, respectively. Moreover we clearly have $B_{x'} = B_x + B_{x'-x}$ on Ω. Thus we

obtain by Remark 2.13(i) as well as the subadditivity and the distribution-invariance of ρ_g that

$$
\begin{aligned}
g(x') - g(x) &= \rho_g(F_{-B_{x'}}) - \rho_g(F_{-B_x}) \\
&\leq \rho_g(F_{-B_{x'-x}}) \\
&\leq \rho(F_{-B_{x'-x}}) \\
&\leq \sup_{y \in (0,1]} \frac{\rho(F_{-B_y})}{y^\beta} \, (x' - x)^\beta.
\end{aligned}
$$

for every $g \in \mathcal{G}_\rho$. Therefore condition (15) implies that every $g \in \mathcal{G}_\rho$ is Hölder-β-continuous on $(0, 1]$ with Hölder constant L. Since every g is also continuous at 0, we conclude that every $g \in \mathcal{G}_\rho$ is Hölder-β-continuous even on $[0, 1]$ with Hölder constant L.

A Examples for distribution-invariant coherent risk measures on Orlicz spaces

Here we intend to illustrate conditions (11), (12) and (15) by means of examples. At the beginning we will see that the cutting condition (11) and condition (12) are already satisfied if the domain $\mathfrak{X}$ of the coherent risk measure ρ is chosen to be an Orlicz space. Thereafter, in Sections A.1 and A.2, we will give examples for risk measures on Orlisz spaces that satisfy also condition (15). We will show in particular that some of these examples are not covered by the results of Section 2.1 (which justifies Section 2.2).

Recall that a continuous Young function is a convex function $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ satisfying $\psi(0) = 0$, being continuous at 0, and converging to ∞ as $x \to \infty$. Every continuous Young function is in particular nondecreasing. For any continuous Young function ψ, the set

$$
\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P}) := \left\{ Y \in \mathcal{L}^0(\Omega, \mathcal{F}, \mathbb{P}) \, : \, \mathbb{E}[\psi(|Y|/c)] < \infty \text{ for some } c > 0 \right\}
$$

is known as Orlicz space associated with the Young function ψ, whereas the subset

$$
\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P}) := \left\{ Y \in \mathcal{L}^0(\Omega, \mathcal{F}, \mathbb{P}) \, : \, \mathbb{E}[\psi(|Y|/c)] < \infty \text{ for all } c > 0 \right\}
$$

is sometimes called Orlicz heart associated with the Young function ψ (cf. [6]). For any continuous Young function ψ we have $\mathcal{L}^\infty(\Omega, \mathcal{F}, \mathbb{P}) \subset \mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P}) \subset \mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P}) \subset \mathcal{L}^1(\Omega, \mathcal{F}, \mathbb{P})$. For the particular continuous Young function $\psi(x) = x^p$ with $p \in [1, \infty)$, the spaces $\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ and $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ coincide with $\mathcal{L}^p(\Omega, \mathcal{F}, \mathbb{P})$. For details the reader is kindly referred to [30] or [10, Section 2].

Lemma A.1 *If $\mathfrak{X}$ is one of the spaces $\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ or $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ for some continuous Young function ψ, then every coherent risk measure $\rho : \mathfrak{X} \to \mathbb{R}$ satisfies the cutting condition (11) as well as condition (12).*

Proof The sets $L^\psi(\Omega, \mathcal{F}, \mathbb{P})$ and $M^\psi(\Omega, \mathcal{F}, \mathbb{P})$ of all equivalence classes of $\mathbb{P}$-almost everywhere equal elements of $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ and $\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ (respectively) are known to be vector spaces. The (Luxemburg) norm,

$$\|Y\|_\psi := \inf\left\{c > 0 \,:\, \mathbb{E}[\psi(|Y|/c)] \leq 1\right\}, \qquad Y \in L^\psi(\Omega, \mathcal{F}, \mathbb{P}),$$

makes $L^\psi(\Omega, \mathcal{F}, \mathbb{P})$ a Banach space with $M^\psi(\Omega, \mathcal{F}, \mathbb{P})$ being norm-closed. (Notice that for $\psi(x) = x^p$, with $p \in [1, \infty)$, the Luxemburg norm coincides with the classical L^p-norm $\|\cdot\|_p$.) As a consequence $(L^\psi(\Omega, \mathcal{F}, \mathbb{P}), \|\cdot\|_\psi)$ and $(M^\psi(\Omega, \mathcal{F}, \mathbb{P}), \|\cdot\|_\psi)$ are Banach lattices (with respect to the $\mathbb{P}$-almost sure ordering $\succeq$), i.e. Banach spaces such that $\|Y\|_\psi \geq \|X\|_\psi$ whenever $Y \succeq X$. Therefore every real-valued coherent risk measure ρ on $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ or $\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ is continuous w.r.t. the seminorm on $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ associated with $\|\cdot\|_\psi$ (cf. [33, Proposition 3.1]).

Below we will show that

$$\lim_{r \to \infty} \|Y_r\|_\psi = 0 \tag{20}$$

for every decreasing sequence $(Y_r)_{r \geq 0} \subset L^\psi(\Omega, \mathcal{F}, \mathbb{P})$ (resp. $\subset M^\psi(\Omega, \mathcal{F}, \mathbb{P})$) converging $\mathbb{P}$-almost surely to 0 as $r \to \infty$. On the one hand, (20) implies $\lim_{r \to \infty} \|\lambda(X - r)^+\|_\psi = 0$ for every $X \geq 0$ in $L^\psi(\Omega, \mathcal{F}, \mathbb{P})$ (resp. in $M^\psi(\Omega, \mathcal{F}, \mathbb{P})$) and $\lambda > 0$. Along with the seminorm-continuity of the risk measure ρ established above, this would imply that the cutting condition (11) holds. On the other hand, (20) also implies $\lim_{x \to 0+} \|F_{B_x}^\leftarrow(U)\|_\psi = 0$, where $F_{B_x}^\leftarrow$ denotes the left-continuous inverse of the df F_{B_x} of the Bernoulli distribution with parameter x, and U is a random variable on $(\Omega, \mathcal{F}, \mathbb{P})$ which is uniformly distributed on $(0, 1)$. Along with the seminorm-continuity of the risk measure ρ established above, this would imply that condition (12) holds.

It remains to show (20). For any decreasing sequence $(Y_r)_{r \geq 0} \subset L^\psi(\Omega, \mathcal{F}, \mathbb{P})$ (resp. $\subset M^\psi(\Omega, \mathcal{F}, \mathbb{P})$) converging $\mathbb{P}$-almost surely to 0, the sequence $(\|Y_r\|_\psi)_{r \geq 0}$ is decreasing as well. Moreover, for any $0 < c \leq \inf_r \|Y_r\|_\psi$ the decreasing sequence $(\psi(|Y_r|/c))_{r \geq 0}$ converges $\mathbb{P}$-almost surely to 0 due to the continuity of ψ. By dominated convergence we deduce $\lim_{r \to \infty} \mathbb{E}[\psi(|Y_r|/c)] = 0$, which in turn implies $\inf_r \|Y_r\|_\psi = 0$. This yields in particular (20). $\qquad\square$

In the following Sections A.1 and A.2, we will present some customary distribution-invariant coherent risk measures on Orlisz spaces that satisfy also condition (15) (apart from conditions (11) and (12)).

A.1 Haezendonck risk measures

Let ψ be a strictly increasing continuous Young function satisfying $\psi(1) = 1$, and let $\mathfrak{X}$ be the Orliz heart $\mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ associated with ψ. Moreover fix $\alpha \in (0, 1)$. It was shown in [14] that for every $X \in \mathcal{M}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ and every $x \in \mathbb{R}$ with $\mathbb{P}[X > x] > 0$ there exists a unique real number $\pi_\alpha^\psi(X, x) > x$ such that

$$\mathbb{E}\left[\psi\left(\frac{(X - x)^+}{\pi_\alpha^\psi(X, x) - x}\right)\right] = 1 - \alpha.$$

Therefore we may define a functional $\rho_\alpha^{H,\psi}$ on the set $\mathbb{F}^\psi$ of all df F_X of random variables $X \in \mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ by

$$\rho_\alpha^{H,\psi}(F_X) := \inf \left\{ \pi_\alpha^\psi(-X, x) \,:\, x \in \mathbb{R} \text{ with } \mathbb{P}[-X > x] > 0 \right\}.$$

The functional $\rho_\alpha^{H,\psi}$ provides a distribution-invariant positively homogeneous risk measure (cf. [14, Theorem 3.2]) known as Haezendonck risk measure w.r.t. ψ and level α. The restriction of $\rho_\alpha^{H,\psi}$ to the set of all df of $\mathbb{P}$-essentially bounded random variables has been established to be subadditive in Proposition 12 of [3]. The proof given there can be transferred verbatim to the functional on $\mathcal{L}^\psi(\Omega, \mathcal{F}, \mathbb{P})$ itself. So, in fact, $\rho_\alpha^{H,\psi}$ provides a distribution-invariant coherent risk measure. According to Lemma A.1 it also satisfies the cutting condition (11) and condition (12). By the way, there is an intimate relationship with Orlicz premiums as introduced in [15]. Indeed: The number $\pi_\alpha^\psi(X, x) - x$ can be seen as the Orlicz premium of $(X - x)^+$ w.r.t. ψ.

The following lemma shows that under some additional assumptions on ψ the Haezendonck risk measure $\rho_\alpha^{H,\psi}$ also satisfies condition (15), so that it meets the requirements discussed subsequent to (10).

Lemma A.2 *If there are some $x_0 \in (0, 1 - \alpha)$ and $\beta \in (0, 1]$ such that*

$$x\,\psi(x^{-\beta}) \leq 1 - \alpha \qquad \forall\, x \in (0, x_0], \tag{21}$$

then the Haezendonck risk measure $\rho_\alpha^{H,\psi}$ satisfies condition (15). For instance, condition (21) is satisfied for $\psi(x) = x^p$ with $p \in [1, \infty)$.

Proof We have for $x \in (0, 1)$

$$\rho_\alpha^{H,\psi}(F_{-B_x}) \;\leq\; 1 \wedge \pi_\alpha^\psi(B_x, x) \;=\; 1 \wedge \left(x + \frac{1 - x}{\psi^{-1}((1 - \alpha)/x)} \right).$$

where ψ^{-1} denotes the inverse of ψ (recall that we assumed the Young function ψ to be strictly increasing). Under assumption (21) we can easily deduce with the help of (14) that

$$\sup_{x \in (0,1]} \frac{\widetilde{g}_{\rho_\alpha^{H,\psi}}(x)}{x^\beta} \;=\; \sup_{x \in (0,1]} \frac{\rho_\alpha^{H,\psi}(F_{-B_x})}{x^\beta} \;\leq\; \max\{2; x_0^{-\beta}\}.$$

That is, (15) holds. In the case $\psi(x) = x^p$, with $p \in [1, \infty)$, condition (21) is easily seen to hold for $\beta := (2p)^{-1}$ and $x_0 := (1 - \alpha)^2$. This verifies the second statement of the lemma. $\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\square$

Now, choose $\psi(x) = x^p$ for any $p \in [1, \infty)$. For some choices of p the corrsesponding Haezendonck risk measure degenerates to a distortion risk measure, so that also the results of Section 2.1 could be applied. For instance, for $p = 1$ the Haezendonck risk measure $\rho_\alpha^{H,\psi}$ is just the Avarage Value-at-Risk at level $1 - \alpha$ (see [13, Lemma 4.46] and [3, Section 3.1]). For other choices of p, the coherent risk measure $\rho_\alpha^{H,\psi}$ does not degenerate to a distortion risk measure (cf. Example A.3). This justifies the investigations of Section 2.2.

Example A.3 *For $\psi(x) = x^2$ and $\alpha \in (\frac{1}{3}, \frac{3}{8})$ the Haezendonck risk measure $\rho_\alpha^{H,\psi}$ is not a distortion risk measure.*

Proof According to Remark 2.13(ii) it suffices to show that $\rho := \rho_\alpha^{H,\psi}$ does not coincide with the distortion risk measure $\rho_{\widetilde{g}_\rho}$, where $\widetilde{g}_\rho$ denotes the distortion function associated with ρ (cf. (13)). We will show that $\rho(-Y) \neq \rho_{\widetilde{g}_\rho}(-Y)$ for every random variable Y which is uniformly distributed on $\{0; 1; 2\}$. On the one hand, for the Haezendonck risk measure we obtain

$$\rho(-Y) \leq \pi_\alpha^\psi(Y, 1/3) = 1/3 + \left(\frac{\mathbb{E}[((Y - 1/3)^+)^2]}{(1 - \alpha)} \right)^{1/2} < 5/3.$$

On the other hand, for the associated distortion function $\widetilde{g}_\rho$ we obtain by straightforward calculations

$$\widetilde{g}_\rho(x) = \begin{cases} x + \left(\frac{\alpha}{1-\alpha} x(1-x) \right)^{1/2} & : \ x < 1 - \alpha \\ 1 & : \ x \geq 1 - \alpha \end{cases}$$

and thus

$$\rho_{\widetilde{g}_\rho}(-Y) = \widetilde{g}_\rho(1/3) + \widetilde{g}_\rho(2/3) = \frac{2}{3} \left(\frac{2\alpha}{1-\alpha} \right)^{1/2} + 1 \geq \frac{5}{3}.$$

Therefore we indeed have $\rho(-Y) \neq \rho_{\widetilde{g}_\rho}(-Y)$. $\qquad\qquad\square$

A.2 Risk measures based on one-sided moments

Let $\mathfrak{X}$ be $\mathcal{L}^p(\Omega, \mathcal{F}, \mathbb{P})$ for some $p \in [1, \infty)$ and let $a \in [0, 1]$. Then

$$\rho_{p,a}(F_X) := -\mathbb{E}[X] + a \left(\mathbb{E}[((X - \mathbb{E}[X])^-)^p] \right)^{1/p}$$

defines a distribution-invariant coherent risk measure on the set $\mathbb{F}^p$ of all df F_X of random variables $X \in \mathcal{L}^p(\Omega, \mathcal{F}, \mathbb{P})$ (cf. [12, Lemma 4.1]). The risk measure $\rho_{p,a}$ has been introduced in [12] as a building block for the problem of risk allocation (actually it was studied earlier in [8] on $\mathcal{L}^\infty(\Omega, \mathcal{F}, \mathbb{P})$ in a different context). In view of Lemma A.1 it also satisfies the cutting condition (11) and condition (12). Moreover, the following lemma tells us that it also fulfills condition (15), so that it meets the requirements discussed subsequent to (10).

Lemma A.4 *The risk measure $\rho_{p,a}$ satisfies condition (15) for every $\beta \in (0, 1/p)$.*

Proof It can be easily verified that the associated distortion function $\widetilde{g}_{\rho_{p,a}}$ of $\rho_{p,a}$ satisfies $\widetilde{g}_{\rho_{p,a}}(x) = x + a(1 - x)x^{1/p}$, which immediately yields the statement of the lemma. $\qquad\qquad\square$

In the case $a = 0$ the risk measure $\rho_{p,a}$ degenerates to the negative mean which is a distortion risk measure with the identity on $[0, 1]$ as distortion function. A similar statement does not hold for $a > 0$, as will be shown in the following lemma.

Lemma A.5 *If $a > 0$, then the risk measure $\rho_{p,a}$ is not a distortion risk measure.*

Proof   According to Remark 2.13(ii) it suffices to show that $\rho := \rho_{p,a}$ does not coincide with the distortion risk measure $\rho_{\widetilde{g}_\rho}$, where $\widetilde{g}_\rho$ denotes the distortion function associated with ρ (cf. (13)). We will show that $\rho(-Y) \neq \rho_{\widetilde{g}_\rho}(-Y)$ for every random variable Y which is uniformly distributed on $\{0; 1; 2\}$. One the one hand, we have $\rho_{p,a}(-Y) = 1 + a(1/3)^{1/p}$. On the other hand, we easily obtain $\widetilde{g}_{\rho_{p,a}}(x) = q + a(1 - x)x^{1/p}$, and so

$$\rho_{\widetilde{g}_\rho}(-Y) \;=\; \widetilde{g}_\rho(1/3) + \widetilde{g}_\rho(2/3) \;=\; 1 + a(1/3)^{1/p}(2 + 2^{\frac{1}{p}})/3.$$

That is, $\rho(-Y) \neq \rho_{\widetilde{g}_\rho}(-Y)$. □
